EFFECTS OF PARTIAL ACIDULATED PHOSPHATE ROCK AND COMPOST ON ADSORPTION AND DESORPTION CAPACITIES OF COPPER IN CALCAREOUS SOIL

^aAl-Rubaye, M.A. & ^bAlganabi, F.K.

^aSoil and water resources sciences department, College of Agriculture, University of Baghdad, Iraq ^bDepartment of Research and Studies, Horticulture office, Ministry of Agriculture, Iraq *corresponding author email: moshahtool@gmail.com

ABSTRACT

In this present laboratory study , partial acidulated phosphate rock (40% PAPR) and composed have been used to study their effects on adsorption and desorption capacities of copper in calcareous ,Iraqi soil .The results showed increases capacity of soil to adsorb copper with increasing concentrations of the added copper in presence of PAPR and compost. Adsorption curves showed two phases ,first phase was rapprochement values of copper adsorption of the copper added solutions 2.5,5.0 and 10 mg Cu L⁻¹, and second phase was different values of copper adsorption at concentrations 25,50 and 100 mg Cu L⁻¹. The percentage of copper adsorption capacity took the following ranking in the used treatments (soil+compost) > (soil) >(soil+compost+40% PAPR).Desorption study of the adsorbed copper showed decrease desorption capacity values with increase of the adsorbed copper amounts in compost and 40% PAPR treatments .The attainted adsorbed copper was 82.23% at 2.5 mg Cu L⁻¹ solution and 52.23% at 10 mg Cu L⁻¹ solution .The desorption capacity of copper values were highest in (soil) treatment followed by (soil+ compost) treatment and lowest in (soil +compost+40% PAPR) treatment.

KEYWORDS: Adsorption isotherm curve, PAPR, Compost, Adsorption and desorption capacities.

INTRODUCTION

Copper is an important micronutrient and trace amounts are essential for crop growth. However, high concentrations of copper will produce toxic effects. Copper involves with many metabolic processes in plants and activates of many enzymes and has positive effects in growth and yield of many crops (Alloway, 1995). For most agricultural soils, bioavailability of Cu²⁺ is controlled by adsorption process (Xie.1996). There are two types of minerals that are involved in the adsorption - desorption Cu²⁺ :permanent charge and variable charge. of Permanent Charge minerals such as montmorillonite carry a negative charge as a result of ion substitution during the formation of minerals (Bertsch and Seaman, 1999). In spite of having the most soils acceptable of total copper the available amount of copper is considered as a limiting and important factor and presence of high organic matter or high level of phosphorus may either decrease or increase its availability in soil (Kabata-Pendias, 2001). Organic matter binds copper more tightly than other micronutrients and this reduces availability to crops and then sufficient copper is released to support normal crop growth after decomposing of organic matter (Schulte and kelling, 1999). The adsorption is considered one out the important processes in soil that may effect on fate and movement of the nutrients such as P, K ,S, Cu ,Zn ,Mn and Bo (Hunter, 1980), while the adsorption capacity is the relation between the amount of the adsorbed matter by the solid part of soil and its quantity in soil solution at equilibrium . Adsorption mechanisms of copper on soil oxides ,clay minerals and organic matter were studied by many workers such as Yu et al (2002) ; Xiong (2005);Shariff and Esmail (2012);Das et al (2013) ; Alganabi and Al-Rubaye(2016).The desorption capacity is the amount of the released nutrient to soil solution compared with its adsorbed amount. The physical and chemical properties of soil ,soil minerals and organic matter are considered as important factors affecting copper desorption (Singh et al,1994 ; Yu et al,2002; Yuan et al.2007;Abat,2010 , Shariff and Esmael,2012). The overall objectives of this study are to quantify soil copper adsorption – desorption behavior and study effects of adding compost and 40% PAPR on adsorption and desorption of copper.

MATERIALS AND METHODS Soil and treatments

Soil samples were collected from college of agriculture field ,Abu-ghraib, Baghdad, Iraq. Composite soli sample was air dried ,ground, and passed through a 60-mesh sieve to use. Some of the soil chemical and physical properties are given in Table 1.Three kinds of treatments were chosen in this study, they were Soil, (Soil+Compost)+and (soil +Compost +40%PAPR,partial acidulated phosphate rock) ,the weights of soil, compost and 40%PAPR were 5g ,10g compost kg⁻¹soil and 20g PAPR kg⁻¹soil respectively. Some of the chemical properties of the used compost are shown in Table 2. The phosphate rock(PR) was brought from Akashat region, Al-Ramade governance, Iraq and some of its chemical properties are shown in Table 3. Enough amount of this PR was treated with concentrated H_2SO_4 at rate to produce 40% PAPR by using the method that was suggested by Yagodin (1984).

#### Adsorption capacity of copper ion

The materials of the last three treatments were placed into 100 ml polypropylene centrifuge tubes, and 50 ml of solution containing 0,2.5,5,10,25,50 and 100 mg Cu L ¹(equal to 0,25,50,100,250,500 and 1000 mg C kg⁻ ¹soil)(as Cu(NO₃)₂) was added to each tube. The suspensions were shaken at 200 rpm for 2h at 25 centigrade and then equilibrated in a dark incubator for an additional 22h .At the end of designated time ,the suspensions were centrifuged at 2500 rpm for 10 min and filtered through 0.45-um filter paper .Ten milliliters of the filtrate were transferred into a 10 ml polypropylene centrifuge tube for measuring Cu²⁺ concentration using atomic absorption spectrometry .Total amount of the adsorbed  $Cu^{2+}$  (q) was calculated by the difference between the total applied  $Cu^{2+}$  in the equilibrium solution(Yu. et al,2002).

#### Desorption capacity of adsorbed copper ion

The residue Cu-enriched soil separated from the supernatant solution by centrifugation ,from the above adsorption experiment ,was treated with 50ml-0.005M DTPA to each tube and the suspensions were shaken at 200 rpm for 2h at 25centigrate and equilibrated for an additional 10h . The equilibrated suspensions were then centrifuged at 2500 rpm for 10 min and then filtered .Ten milliliters of the filtrate were pipetted into a 10 ml polypropylene centrifuge tube for measuring Cu²⁺ concentration using atomic absorption spectrometry (Yu. et al, 2002).

# RESULTS

### Adsorption capacity of copper ion

Table 4-shows that adsorption of Cu2+ increased with increase of Cu concentration in the equilibrium solution in soil, (soil+compost) and (soil+compost+40%PAPR) treatments. Adding compost gave the highest values of the adsorbed Cu2+ compared with the other treatments. The adsorbed copper concentrations the composed added treatment were 19.36 and 793.68 mg.Cu kg-1 soil for Cu2+ solutions 25 and 1000 mg Cu.kg-1soil respectively. This result reflects the role of organic matter to bind strongly copper ions (Alganabi and alrubaye, 2016) . Slopes of the isotherms curves (Fig. 1) reflected high adsorption capacity in soil,( soil+compost) and (soil+compost+40%PAPR) treatments ,possibly because Cu²⁺ involves multiple adsorption sites (McBride,1995 and Alcacio et al,2001) and the high capability for calcareous (carbonate minerals) to adsorbed and precipitate Cu²⁺ as CuCO₃(Kabata-Pendias,2011). Using compost gave the highest slope of the adsorption isotherms, It is possibly due to high C.E.C of soil and organic matter colloids and the high affinity of organic matter to adsorbed copper (Kabata-Pendias, 2011). Adding 40% PAPR gave the lowest slopes of adsorption isotherms. This may be due to the high competition between P and Cu on adsorption sites of the organic and clay colloids (Alneame, 1999 and Kabata-Pendias, 2011). The used soil adsorbed more than 79% of the copper in the 1000 mg Cu kg⁻¹soil concentration , suggesting that the soil might not reach its maximum adsorption capacity even at the

## Desorption capacity of the adsorbed copper ion

Most of the adsorbed  $Cu^{2+}$  in the soil ,(soil+compost) and (soil+compost+40%PAPR) treatments was readily desorbed by 0.005M-DTPA.It can be noticed that the percentage of the desorbed copper from the soil treatment ranged from 59.59% for the adsorbed value 792.23 mg Cu kg⁻¹ soil to 82.23% for the adsorbed value 19.28 mg Cu Kg⁻¹

¹soil ,This means that from 17.77% to 40.41% of the total adsorbed  $Cu^{2+}$  was recovered by DTPA (Table 5 and Fig. 2).The proportion of the desorbed  $Cu^{2+}$  decreased with increase the concentration of adsorbed  $Cu^{2+}$  and these may reflect high tightly bonded between copper and soil collides (McLaren and Grawford, 1973).

**FIGURE 2**. The relation between percentage of the desorbed  $Cu^{2+}$  with concentration of the adsorbed  $Cu^{2+}$  in (soil) treatment.

Mixing the compost with soil gave a range of desorption rate of copper from 81.93% for the adsorbed value 19.36 mg Cu kg⁻¹soil to 52.78% for the adsorbed value 793.68 mg Cu Kg⁻¹soil (Table 5 and Fig. 3).This may be probably

due to the fact that organic matter is the affected factor in fixation of the micronutrients such as  $Cu^{2+}$  by increasing the adsorbed amount of copper (Robert, 1983).

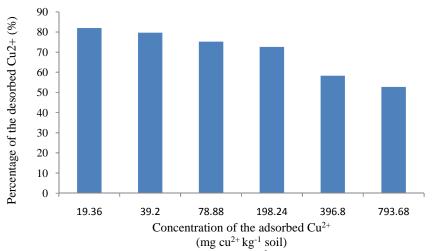

FIGURE 3. The relation between percentages of the desorbed Cu²⁺ with concentration of the adsorbed Cu²⁺ in (soil+compost) treatment

The percentages of the desorbed copper when compost and PAPR were mixed with the soil are shown in Table 5 and Fig 4. The desorbed copper percentages were 81.70 ,78.59 ,75.49 ,65,18 ,66.44 and 52.32% for the adsorbed copper values 19.2 ,78.56 ,197.28 ,394.64 and 788.56 mg Cu Kg⁻¹soil respectively. This treatment resulted less values of the desorbed copper compared with (soil) and (soil+compost) treatments and this may be probably to increase the surface area of soil organic and mineral colloids and clay minerals and PAPR and then, the adsorbed copper amounts increased while their desorption amounts decreased (Liu et al,2011;Alrubaye et al,2016 and Alganabi and Al-Rubaye,2016).

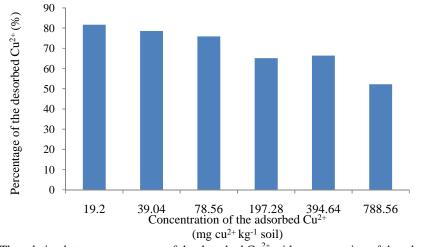

FIGURE 3. The relation between percentage of the desorbed Cu²⁺ with concentration of the adsorbed Cu²⁺ in (soil+compost+40%PAPR) treatment
