**ABSTRACT**
Biofertilizers are cost-effective and renewable source of plant nutrients to supplement the parts of chemical fertilizers. The present research study entitled “Effect of Integrated Nutrient Management on growth and seed yield of field pea (*Pisum sativum var. arvensis*)” was conducted in *Rabi* season 2015-2016 at the Field Experimentation Centre of Department of Genetics and Plant Breeding, Sam Higginbottom Institute of Agriculture, Technology and Sciences, Allahabad in RBD (Randomized Block Design) with three replication and 11 treatments. The results showed that the effect of integrated nutrient management was significant on growth and yield parameters of field pea. In field observation where highest mean performance of No. of branches/plant (19.00), No. of seed/pod (8.13), No. of pods/plant (16.40), Pod length (8.83cm), pod weight/plant (39.47g), plant height (78.31cm), Biological yield (54.07g), Harvest index (49.30), Seed yield/plant (30.47g) etc. were observed by T3 as compared to control with mean value of (9.60, 4.60, 8.93, 5.13cm, 29.53g, 68.53cm, 38.87g, 55.92, 18.80g respectively). Thus, It showed that the treatment T3 (100% RDF + *Rhizobium* @20 g/kg seed) was identified as a desirable treatment with respect of growth & seed yield of field pea.

**KEYWORDS**: Field pea, Integrated Nutrient Management, Seed Yield.

**INTRODUCTION**
Field pea (*Pisum sativum L.*) is a highly nutritive *Rabi* season legume containing high percentage of digestible protein, along with carbohydrates, vitamin A, C, calcium and phosphorus. Use of inorganic fertilizer alone is injurious to soil health and soil productivity. Use of organic and bio-fertilizers enhances crop production and sustain soil heath (Akbari *et al*., 2011). India accounts for 33% of the world area 22% of the world production of pulses. The major pulse crop grown in India are chickpea, pigeon pea, lentil, moong bean, urd bean and field pea. About 90% of the global pigeon pea, 65% of chick pea 37% of lentil area falls in India, corresponding to 93%, 68% and 32% of the global production, respectively (FAOSTAT, 2013).

Biofertilizers are known to play an important role in increasing availability of nitrogen and phosphorus besides improving biological fixation of atmospheric nitrogen and enhance phosphorus availability to crop. Introduction of efficient strains of *Rhizobium* in soils with low nitrogen may help augment nitrogen fixation and there by boost production of crops. Phosphorus is known to play an important role in growth and development of the crop and have direct relation with root proliferations, straw strength, grain formation, crop maturation (Bhat *et al.* (2013). Phosphorus and potassium application had significant effect on vine length while their interaction indicated non-significant differences among the treatment means. The result indicates that the vine length significantly increased with the increasing rate of phosphorus and potassium up to 69kg P2O5 and 100 kg K2O ha\(^{-1}\) respectively (Akhtar *et al.* (2003). Integrated nutrient management (INM) plays a vital role to maintain soil fertility, to bring stability, sustainability in agricultural production and also avoid over dependence on chemical fertilizers. Efficient use of integrated plant nutrient supply system is a prerequisite for achieving continuous advances in biological productivity of vegetable crops in ecologically sustainable manner (Sreenivas *et al.*, 2000). Keeping in this view the present research study was conduct to assess the Effect of Integrated Nutrient Management on growth and seed yield of field pea.

**MATERIALS AND METHODS**
The research experiment was conducted during *Rabi* 2015-2016 at Field Experimentation Centre of the Department of Genetics and Plant Breeding, Allahabad School of Agriculture, Sam Higginbottom Institute of Agriculture, Technology & Science, Deemed-to-be-University, Allahabad. The Pea variety PSM-3 was selected for this research trial and seed source is Indian Institute of Pulse Research (IIPR) Kanpur (U.P.) India. The gross area of field is about 154 m\(^2\) and net area 132 m\(^2\) respectively. Seeds were sown in line sowing method with 30 cm row to row spacing and 10 cm plant to plant spacing respectively. The soil of the experimental field was sandy loam and having \(pH\) 7.5. The Application of fertilizer was given at the time of sowing and recommended dose of fertilizer @30:60:40 NPK 20 kg/ha was applied in the form of urea, single super phosphate and mulate of potash respectively as basal dose at the time of sowing and recommended dose of biofertilizers treatments as *Rhizobium* (20 gm/kg seed), *Pseudomonas* (20gm/ kg seed), Carbendazim (3gm/kg seed) where T0- control, T1- 100% RDF, T2-
Rhizobium, T, Psuedomonas, T, Car ben dazim, T, 100% RDF + Rhizobium, T, 100% RDF + Psuedomonas, T, 100% RDF + Car ben dazim, T, Rhizobium + Psuedomonas, T, Rhizobium + Car ben dazim, T, Psuedomonas + Car ben dazim. The experiment was carried out in Randomized block design with 11 treatments included Bio fertilizers and Chemical fertilizers (Psuedomonas, Car ben dazim, Rhizobium). The following observations were recorded such as growth parameters Plant height(cm), Days to 50% flowering, No. of branches/plant, and Yield and yield characters, Number of pods per plant, seed yield per plant (kg), No. of seed/ pod, days to maturity, Nodules /plant, pod weight/plant(gm), pod length(cm), Biological yield (gm), Harvest index etc.

RESULTS & DISCUSSION
The results showed significant difference was observed for all of the treatments at 5% level of significance. The effect of integrated nutrient management on growth and seed yield characters were also found significantly.

Plant Height (cm) & No. of branches/plant
In field observation where mean performance of plant height at maturity stage ranged from 68.53 cm to 77.91 cm with mean value of 73.42. Maximum plant height (78.31 cm) was recorded by T2 as compared to control with mean value of (68.53cm) The mean performance for number of branches per plant at maturity stage ranged from 9.6 to 19 with mean value of 14.3. Maximum number of branches (19.00) was recorded by T5 as compared control with mean value of (9.60). Bapi das et al., (2011) evaluate the effect of 16 treatments i.e. various sources of nutrient on growth parameter, yield attributes, nutrient uptake, and soil nutrient status of cowpea (Vigna unquiculata L.) variety ‘pusa komol’. As regards the growth parameters the plant height, number of leaves and branches per plant were significantly increased to a greater extent by the treatment 75 per cent RDF + Vermicompost + Rhizobium + PSB as compared to RDF alone at the field of Horticulture farm, Department of Horticulture, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola (Maharashtra). Patel et al. (1998) conducted at Indore in Madhaya Pradesh, showed that application of rhizobium culture and phosphate solubilizing bacteria in combination with 50% of N&P significantly increased plant height, pods/plant, grains/pod and ultimately pod yield over control and chemical fertilizers alone.

</table>

No. of pods/plant & Pod Length (cm)
The mean performance of number of pod per plant ranged from 8.93 to 15.87 with mean value of 12.4. Maximum number of pods per plant (15.87) was recorded by T5 as compared to control with mean value of (8.93). The mean performance of pod length (cm) ranged from 5.13 to 8.83 with mean value of 6.98. Maximum number of pod length (8.83) was recorded by T3 as compared to control with mean value of (5.13). Bapi das et al. (2011) evaluate the effect of 16 treatments i.e. various sources of nutrient on growth parameter, yield attributes, nutrient uptake, and soil nutrient status of cowpea (Vigna unquiculata L.) variety ‘pusa komol’. In respect of yield per hectare and over all yield contributing factors, such as number of pods, diameter and length of pods, the treatment of 75% RDF + Vermicompost + Rhizobium + PSB was found significant over control and RDF alone. It indicates a saving of 25% chemical fertilizer. Nitrogen status in soil after harvest was found significant in treatment RDF + Rhizobium + PSB and phosphorus status in soil after harvest was found significant in treatment 75% RDF + Vermicompost + Rhizobium + PSB. Maximum nitrogen and phosphorus uptake by plant was found significant in treatment 75% RDF + Vermicompost + Rhizobium + PSB. Thus there was increase in soil fertility level by using biofertilizer, FYM, vermicompost along with chemical fertilizer as compared to chemical fertilizers alone at the field of Horticulture farm, Department of Horticulture, Dr. Panjabrao Deshmukh Krishi Vidyapeeth, Akola (Maharashtra). Upadhayay et al. (1999) reported that significant increase in the plant height, number of branches, number of nodules, pods per plant and seed per pod and seed yield when green gram seeds inoculated with Rhizobium compared to no inoculation.
Pod weight/plant & Days to Maturity
The mean performance of pod weight per plant (g) ranged from 29.53 to 39.47 with mean value of 34.5g. Maximum weight (39.47g) was recorded by T9 as compared to control with mean value of (29.53g). The mean performance of Days to maturity ranged from 90.67 to 95.33 with mean value of 93. Maximum day to maturity (95.33) was recorded by T10 as compared to T9 with mean value of (90.67). R. A. Singh (2011) reported that the Integration of 25 kg N + 50 kg P2O5 with residue of 100 q FYM ha-1 significantly increased the pods weight plant-1, grains pod-1, grain weight plant-1 and 100-grain weight, which culminated into significant increase in grain yield. Mishra et al. (2010) A field experiment was conducted during two consecutive Rabi seasons of 2007 and 2008 to study the effect of bio-fertilizers in conjunction with inorganic fertilizers on growth and yield of dwarf field pea (cv. Jai) at Oil Seed Research Farm, Kalyanpur in C.S.A. University of Agriculture and Technology, Kanpur. The experiment was laid out in split plot design with three replications in sandy loam soil. The experiment comprised 32 treatment combinations of four levels of fertility (Control, 50, 75 and 100% RDF) and eight bio-fertilizer treatments (Control, Rhizobium, PSB, PGPR, Rhizobium +PSB, Rhizobium +PGPR, PSB+PGPR and Rhizobium+PSB+PGPR). Results indicated that the combined application of 100% RDF and seed inoculation with Rhizobium+PSB+PGPR improved all the growth; yield attributes and yields offield pea. Fresh and dry weight plant-1, nodules number and dry weight plant-1 were found significantly maximum. Thus, it can be recommended that to obtain the maximum grain yield and net profit from dwarf field pea, seed should be inoculated with Rhizobium+PSB+PGPR and crop should be fertilized with 100% recommended dose of fertilizer.

Number of Seeds/pod & No. of Nodules/plant
The mean performance of Number of seeds per pod ranged from 4.6 to 8.13 with mean value of 6.36. The maximum number of seeds per pod (8.13) was recorded by T5 as compared to control (4.60). The mean performance of Number of Nodules per plant ranged from 21.4 to 28.73 with mean value of 25.06. Maximum number of nodule per plant (28.73) was recorded by T5 as compared to T2 with mean value of (20.87). Mishra et al. (2010) also reported to the effect of biofertilizers in conjunction with inorganic fertilizers on growth and yield of dwarf field pea (cv. Jai) and found that number of pods per plant-1, number of seeds pods-1 at maturity attributed significantly increasing with the application of 100% DRF and seed inoculation of Rhizobium +PSB+PGPR. Gupta and Namdeo (1999), Prasad et al. (2002) and Sarg and Hassan et al. (2003), observed a significant increase in number of nodule/plant in pea crop, when organic amendments and bio-fertilizers are both applied in together combination and also reported by Ramadan (1997) indicated that seed inoculation with Rhizobium, revealed significant effect on all studied morphological characters; i.e. stem length (cm), number of branches, number of leaves and number of nodules/plant compared to un-treated one (control).

Seed yield/plant, Biological yield & Harvest Index
The mean performance of Seed yield per plant ranged from 18.8g to 30.47g with mean value of 24.63. Maximum seed yield per plant (30.47 g) was recorded by T5 as compared to control with mean value of (18.80 g). Data for biological yield per plant ranged from 38.87g to 54.07g with mean value of 46.47g. Maximum biological yield per plant (54.07g) was recorded by T5 as compared to control with mean value of (38.87g). The data for harvest index per plant ranged from 49.3 to 55.92 with mean value of 52.61. Minimum harvest index per plant (49.3) was recorded by T3 as compared to control with mean value of (55.92). J.S. Meena (2015) reported that the application of 100 percent RDF+VC @ 2 t/ha significantly increased the plant height, number of branches per plant, chlorophyll content, total root and effective root nodules, fresh weight and dry weight of nodules, number of pods per plant, number of seeds per pod, seed, biological yield and remained at par with the application of 75 per cent RDF+VC @ 2 t/ha over control. Rather et al. (2010) also find out the effect of biofertilizers (Rhizobium, Azotobacter and phosphate solublizing bacteria (PSB)) application on growth, yield and economics of field pea (Pisum sativum L.). The co-inoculation of all the three bio-fertilizers i.e. Rhizobium, Azotobacter and PSB produced significantly higher growth characters as compared to absolute control and when inoculated them individually. The treatment T5 comprising Rhizobium +Azotobacter +PSB gave highest growth in terms of plant height (45.26 cm), number of branches/plant (4.20), number of leaves/plant.

CONCLUSION
The above findings of results of the study clearly indicated the combination of chemical fertilizers and biofertilizers were significant on increase the growth and yield parameters of field pea. No. of branches/plant (19.00), No. of seed/pod (8.13), No. of pods/plant (16.40), Pod length (8.83cm), pod weight/plant (39.47g), plant height (78.31cm), Biological yield (54.07g), Harvest index (49.30), Seed yield/plant (30.47g) etc. were observed by T9 (100% RDF + Rhizobium @400 g/ha). Thus, It showed that the treatment T9 (100% RDF + Rhizobium @400 g/ha) was identified as a desirable treatment with respect of growth & seed yield of field pea.
